CFD and CSM Geometry Correspondence

Rear edge zoomed close to the wing tip

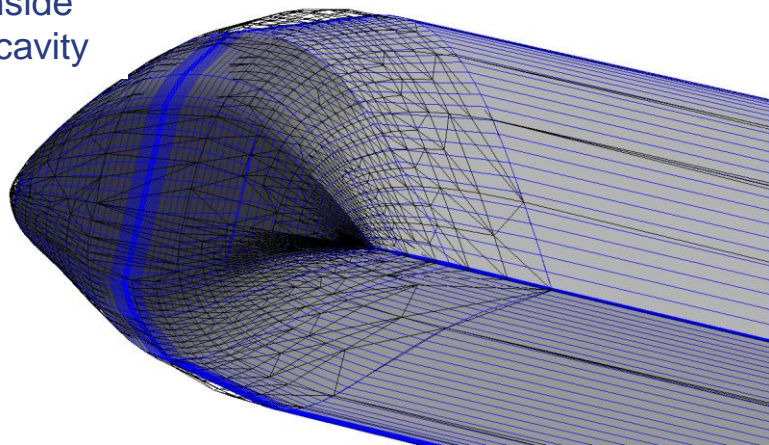

53 k
Nodes

Between edges: 0.8 mm max.

CSM is inside
the CFD cavity

- CSM base: fem_structured_wing.bdf;
- Nastran bdf converted to Abaqus inp;
 - c3d8i FE used;
 - minor modifications of the some nodes location to improve FSI coupling;
 - DOF 1, 2, 3 fixed for PINNED nodes;
 - Excitation SHELLS added.

CFD Polyhedral Mesh

Mesh size: 2.4M, 8.5 M and 13.9 M
Top surface grid density: 1.4 mm
Bottom surface grid density: 20 mm
Prism layer thickness: 1.5 mm
of prism layers: 18
Mesher type: Polyhedral
Wall Thickness: 1e-3 mm
Leading edge grid density: 288
Pts/circle

CFD Mesh Details

CFD + CSM Numerics and Physics

- CFD: Navier Stokes, Finite Volume, Roe FDS or AUSM+, SA & K- ω SST Turbulence, Least Square Gradients
- CSM: C3D8I hex, elastic, minimal damping, n-I geom
- Steady-state, Static Equilibrium
 - Steady state rigid + 3 exchanges with static CSM
 - Transient 1st order, 100 subiterations after exchanges
- Transient Free and Forced
 - 2nd order time, 85 to 170 steps/cycle,
 - 20 to 60 subiterations, convergence criteria CI
- Morphed Mesh (Multiquadric, Radial Basis Function)
- S2S Mapping (least square, shape functions)

Turbulence and slip wall

- SA & K- ω SST
- Only for rigid wing, none for aeroelastic

Conclusions

- Aeroelastic equilibrium
 - Reasonable comparisons to other codes and experiments in lift, drag and displacements
 - Overprediction of shock strength and slightly downstream
 - Aero Analyst is now previewing results (Deryl Snyder)
- Wind-off Vibration Structural model
 - Slight errors in frequencies to experiments
 - Closer to published numerical models
- Wind-on Free Vibration
 - Reasonable comparisons to experiments and other codes
 - Need data for damping coefficients to access structure damping
- Wind-on Forced Vibration 1st flap-bending mode
 - Uncertainty where to apply moment, need experimental details
 - Contradiction between published displacement and acceleration
